|                                                                         | • American Heart Association/American College of Cardiology (AHA/ACC)  
|                                                                         | • National Kidney Foundation |
| Case Studies                                                           | • Utilizing what we've learned |
What Is Cardiorenal Syndrome?

There are many interactions between the heart and kidney. The interaction is bidirectional.

This interaction can induce acute or chronic dysfunction:

1. Heart and kidneys, or
2. In either organ
What Is Cardiorenal Syndrome?

There are many interactions between heart disease and kidney disease.

The clinical importance of such relationships is illustrated by the following observations:

• Mortality is increased in patients with heart failure (HF) who have a reduced glomerular filtration rate (GFR).
• Patients with chronic kidney disease (CKD) have an increased risk of both atherosclerotic cardiovascular disease and heart failure.
• Acute or chronic systemic disorders can cause both cardiac and renal dysfunction.
Understanding the Five Types of Cardiorenal Syndrome

The different interactions that can occur led to the following classification of CRS that was proposed by Ronco et al.:

<table>
<thead>
<tr>
<th>TYPE 1</th>
<th>Acute heart failure (HF) results in acute kidney injury (previously called acute renal failure).</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE 2</td>
<td>Chronic cardiac dysfunction (e.g., chronic HF) causes progressive chronic kidney disease (CKD); previously called chronic renal failure.</td>
</tr>
<tr>
<td>TYPE 3</td>
<td>Abrupt and primary worsening of kidney function due, for example, to renal ischemia or glomerulonephritis causes acute cardiac dysfunction, which may be manifested by HF.</td>
</tr>
<tr>
<td>TYPE 4</td>
<td>Primary CKD contributes to cardiac dysfunction, which may be manifested by coronary disease, HF, or arrhythmia.</td>
</tr>
<tr>
<td>TYPE 5</td>
<td>Acute or chronic systemic disorders (e.g., sepsis or diabetes mellitus) that cause both cardiac and renal dysfunction.</td>
</tr>
</tbody>
</table>
Cardiorenal Syndrome in the Context of Cardiovascular Disease

Risk Factors:
- Dyslipidemia
- Hypertension
- Diabetes
- Smoking
- Obesity

Coronary Artery Disease → Coronary Thrombosis → Myocardial Infarction → Arrhythmias and Loss of Muscle → Sudden Cardiac Death

Neurohormonal Activation → Remodeling → Ventricular Enlargement → Congestive Heart Failure → End-stage Heart Failure → Chronic Kidney Disease

Atherosclerosis → myocardiinfarction

Reference: Adapted from the brochure “Biomarkers: Covering the Continuum of Cardiovascular Disease.”
Cardiorenal Syndrome CVD Context: The Important Role of Laboratory Testing

Risk Assessment

Plaque Instability/Inflammation
- hsCRP • Lp(a)

Arteriosclerosis/Inflammation
- hsCRP • Homocysteine
- Fibrinogen

Dyslipidemia
- Total cholesterol
- HDL-cholesterol
- LDL-cholesterol
- Triglyceride
- Apolipoprotein B
- Apolipoprotein A-1
- Lipoprotein (a)

Diabetes
- Glucose
- HbA1c

Myocardial Infarction
- Cardiac troponin
- CK-MB Mass

Anticoagulation Therapy Monitoring
- PT • aPTT • Platelet-function testing
- Anti-FXa assay for heparin

Heart Failure
- BNP • NT-proBNP

Kidney Disease
- Microalbumin
- Creatinine
- Cystatin C • Albumin

Heart Tissue Remodeling
- *Galectin-3 • ST2

*Galectin-3 assay is under development for the ADVIA Centaur® Immunoassay Systems. Not available for sale. Product availability varies by country.

Diabetes Mellitus

- A metabolic disease in which the body’s blood glucose levels become extremely elevated
- Develops when the body either:
  - Stops responding to insulin, or
  - Stops producing enough insulin
- Types of diabetes:
  - Type 1 and type 2
  - Gestational diabetes
  - Other (e.g., genetic defects in β-cell function, genetic defects in insulin action, diseases of the exocrine pancreas such as cystic fibrosis, drug- or chemically induced)
U.S. Statistics for Diabetes Mellitus Are Staggering

Did you know?

29.1 million people have diabetes.

21.0 million people diagnosed.

...and 8.1 million people undiagnosed—don’t know they have it.

...a 3.3 million increase in 3 years since 2011 CDC report.

We spend $245 billion total on direct and indirect diabetes costs.

Chronic Kidney Disease (CKD)

• When kidneys lose their ability to filter effectively, toxic metabolites build up and cause multi-organ damage.

• End-stage renal disease (ESRD) is very serious. A person with ESRD needs to have a kidney transplant or dialysis treatments.

• The two major forms of dialysis are hemodialysis and peritoneal dialysis.
Mortality of Patients on Renal Replacement (Dialysis and Kidney Transplant)

- Among dialysis patients age 65 and older, mortality is twice as high as for patients who have diabetes.
- Rates of mortality in the prevalent population have declined nearly 25% over the last two decades and 19% since 1999.
- However, today only 50% of dialysis patients, and 82% of those who receive a preemptive transplant, are still alive 3 years after the start of ESRD therapy, illustrating the extreme vulnerability of these patients when compared to the general population.

Kidney Disease: “Kidneys Don’t Hurt”

- Patients with kidney disease do not exhibit overt symptoms.
- Physicians typically do not see signs during an exam until the disease is advanced.
- We need IVD tests to diagnose kidney disease and resolve the “silence.”
Evidence of Kidney Disease: The Symptoms

- Changes in urination
- Swelling of extremities or face
- Fatigue
- Skin rash or itching
- Metallic taste in mouth/ammonia breath
- Nausea and vomiting
- Shortness of breath
- Feeling cold
- Dizziness and trouble concentrating
- Leg/flank pain
Also Staggering—the U.S. Statistics for Chronic Kidney Disease

Did you know?

26 million Americans have kidney disease and don’t know.

One in three American adults are at risk of developing kidney disease.

Medicare spending rose 5.2% in 2012 to $507 billion.

Diabetes is listed as the primary cause of kidney failure in 44% of all new cases.

49,677 people began treatment for kidney failure due to diabetes.

28,924 people with kidney failure due to diabetes are living on chronic dialysis or with a kidney transplant.

## Learning Objectives

| Overview                                                                 | • What is cardiorenal syndrome?  
|                                                                         | • Pathophysiology of how diabetes can impact cardiorenal syndrome |
| The Stats                                                              | • Diabetes in the U.S.  
|                                                                         | • Chronic kidney disease in the U.S. |

|                                                                         | • American Heart Association/American College of Cardiology (AHA/ACC)  
|                                                                         | • National Kidney Foundation |
| **Case Studies**                                                       | • Utilizing what we've learned |
Overall, What Are the Potential Complications of Diabetes?

- Many diabetics already have some of the complications associated with diabetes at the time of diagnosis.
- Major organs of concern:

<table>
<thead>
<tr>
<th>Eye</th>
<th>Nerves</th>
<th>Kidney</th>
<th>Heart and Blood Vessels</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diabetic retinopathy</td>
<td>Diabetic neuropathy</td>
<td>Diabetic nephropathy</td>
<td>Atherosclerosis, hypertension, cardio- and cerebrovascular disease</td>
</tr>
</tbody>
</table>

[Images of eye, nerves, kidney, and heart]
How Does Diabetes Cause Kidney Disease?

- In high-risk groups, the **glomerulus** of the kidney is damaged, causing increased porosity, which eventually prevents them from filtering blood effectively.
- The gradual failing of kidney function results in end-stage kidney failure (ESRD).

Source: www.patient.co.uk/health/diabetic-kidney-disease-leaflet
How Does Diabetes Cause Kidney Disease?

- Consistent hyperglycemia causes abnormal glycosylation of cellular proteins, forming advanced glycation end-products (AGEs).
- AGEs induce abnormal changes in the glomerulus, affecting kidney filtration.
- Abnormalities in extracellular proteins damaging the glomerular basement membrane and capillary loops also occur.
- Formation of oxygen radicals can further damage cells.
- Linkage of proteins in the glomeruli triggers localized scarring, preventing the kidney from effectively filtering blood.

Diabetic Complications: Heart Disease and Stroke

Comparison of Diabetic to General Population

- Heart-disease death rates: **2 to 4x higher**
- Risk of stroke: **2 to 4x higher**
- 75% of diabetics treated for high blood pressure
- 68% of diabetes-related death certificates in 2004 noted heart disease for those >65 years old
- 16% of diabetes-related death certificates in 2004 noted stroke for those >65 years old

Numerous trials (e.g., SOLVD, HOPE, and CHS) have identified diabetes as a major risk for development of heart failure.

Diabetes can cause overt heart failure, independent of atherosclerosis or hypertension, via the development of a diabetic cardiomyopathy.

There is indirect evidence that diabetes frequently causes abnormal heart function, even in the absence of other risk factors.

Multiple mechanisms have been implicated in the causation of heart failure.

Heart Failure Is More Common in Patients with Type 2 Diabetes

Glycemic Control and Risk of Development of HF in Diabetes

HF = heart failure

Did you know?

55.1 million Americans afflicted with CKD and diabetes.

One in three American adults are at risk of developing kidney disease.

We spend $752 billion total on CKD and diabetes, and growing annually.

One out of three people with Type 2 diabetes do not know they have it.

# Learning Objectives

## Overview
- What is cardiorenal syndrome?
- Pathophysiology of how diabetes can impact cardiorenal syndrome

## The Stats
- Diabetes in the U.S.
- Chronic kidney disease in the U.S.

## Cardiorenal Syndrome
- Diabetes complications: kidney disease
- Diabetes complication: cardiovascular disease

## Guidelines
- American Diabetes Association (ADA)
- American Heart Association/American College of Cardiology (AHA/ACC)
- National Kidney Foundation

## Case Studies
- Utilizing what we've learned
First, Why So Many Guidelines?

In 2011, the Institute of Medicine (IOM) defined clinical practice guidelines:

“Statements that include recommendations intended to optimize patient care that are informed by a systematic review of evidence and an assessment of the benefits and harms of alternative care options.”

**Trustworthy guidelines should:**

• Be based on a systematic evidence review developed by a panel of multidisciplinary experts.
• Provide a clear explanation of the logical relationships between alternative care options and health outcomes.
• Provide ratings of both the quality of evidence and the strength of the recommendations.

</tbody>
</table>

AHA and ADA Guidelines: CVD Prevention in Type 2 Diabetes

A1C (Hemoglobin A1C, HbA1c)
<7% is optimal

Blood Pressure
130/80 to 140/90 mm Hg

Cholesterol (Lipids, HDL, LDL)
accent shifted to management of LDL

August 11.
Spot/untimed urine sample—early morning void.

No need for 24-hour collections

Tests to be performed in preferred order:

- **Albumin:creatinine ratio (ACR)**
  - Semiquantitative results using urinalysis strip
  - Reflex quantitative
  - If ACR positive, confirm ACR ≥30 mg/g (≥3 mg/mmol) on a random urine using an early morning collection

- **Protein:creatinine ratio (PCR)**
  - Total protein (automated reading)
  - Total protein (manual reading)

Assess GFR and albuminuria at least annually for patients with CKD and more often for those at higher risk of progression.

Test cystatin C in adults with eGFR 45–50 mL/min/1.73 m² who do not have markers of kidney damage, if CKD confirmation is required.
Why Is ACR Preferred over PCR and Total Protein?

• Albumin:creatinine ratio (ACR) is:
  • The most sensitive and specific measure of kidney damage
  • An accurate predictor of kidney and cardiovascular risk
  • A sound tool to show progression of CKD
  • More precise at low, diagnostically important concentrations

• There are ongoing standardization efforts; protein is difficult to standardize.

• Untimed collections are difficult to standardize; hence results could be misleading.

• **First morning void is preferred**: concentration correlates well with 24-hour excretion and has low intra-individual variability.

• Ratios utilizing creatinine account for the variability of urine albumin or protein concentrations due to urine concentration.

Unlike albumin or protein, creatinine is excreted into urine at a constant rate.

**Value of a ratio test**: Accounts for urine concentration or dilution.
<table>
<thead>
<tr>
<th>ROLE OF:</th>

</tr>
</tbody>
</table>

*Staging may be confounded by treatment because RAS blockade could render microalbuminuric patients normoalbuminuric and macroalbuminuric patients microalbuminuric. Thus, although staging is done according to the current level of albuminuria for practical reasons, the implication of the staging undoubtedly is affected by past history. Therefore, when available, data before the initiation of therapy should be considered for classification purposes.

†Because patients with diabetes often have elevated GFR in the early years after diagnosis, GFR less than 90 mL/min may represent a significant loss of function. Kidney biopsy in these patients can show histological evidence of DKD. Patients with diabetes at increased risk of DKD include those with poor glycemic control, longer duration, hypertension, retinopathy, high-normal albuminuria, nonwhite race, family history of hypertension, CVD, type 2 diabetes, and DKD.

‡Reduction in GFR in patients with diabetes and normoalbuminuria is well described in both type 1 and type 2 diabetes; kidney biopsy in such patients often shows evidence of diabetic glomerulopathy. However, in the absence of histological evidence, these patients should be considered to have diabetes and CKD, which may require further investigation.

**Abbreviations:** DKD = diabetic kidney disease; RAS = renin-angiotensin system; CVD = cardiovascular disease.

# Learning Objectives

| Overview | • What is cardiorenal syndrome?

| Guidelines | • American Diabetes Association (ADA)  
• American Heart Association/American College of Cardiology (AHA/ACC)  
• National Kidney Foundation |
| Case Studies | • Utilizing what we've learned |
Case Study: In-hospital Patient

• A 58-year-old, nonsmoking, obese man presents for the treatment of heart failure.

• Past medical history includes type 2 diabetes, hypertension, and dyslipidemia. Treatment is prescribed in accordance with current conditions.

• Physical exam: blood pressure (BP) 152/92 mm Hg, P 68/min and regular, and body mass index 33.

• Jugular venous pressure is not visible. There is +1 peripheral edema.

Case Study: In-hospital Patient

Diagnostic Testing

- HbA1c
- BNP/NT-proBNP
- Troponin for risk stratification may be considered
- Albumin:creatinine ratio (ACR)
- eGFR/creatinine/cystatin C

Case Study: Ambulatory Geriatric Patient

ABOUT THE PATIENT:

• 92-year-old male discharged after acute heart failure episode with CKD
• History of hypertension
• Five-part CABG 40 years in the past
• History of diabetes; no smoking or no hyperlipidemia

What testing would you do to follow up on this patient?

HbA1c
NT-proBNP
ACR
(Albumin, Creatinine, Albumin:Creatinine Ratio)
Case Study: Ambulatory Geriatric Patient

What is the goal of treatment?

Balance of kidneys and heart function
